This collection of information is required by 37 CFR 1.51. The information is used by the public to file (and by the PTO to process) a provisional application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 8 hours to complete, including gathering, preparing, and submitting the complete provisional application to the PTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, Washington, D.C., 20231. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Mail Stop Provisional Application, Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.

LOW TRANS-FATTY ACID FATS AND FAT COMPOSITIONS AND METHODS  
OF MAKING SAME

CROSS REFERENCE TO RELATED APPLICATION

- [0001] This is a continuation-in-part of U.S. Application No. 10/750,457, entitled "Low Trans-Fatty Acid Fat Compositions; Low-Temperature Hydrogenation, e.g., of Edible Oils" and filed 31 December 2003, and claims the benefit of U.S. Provisional Application Nos. 60/525,914, filed 30 November 2003, and 60/492,160, filed 31 July 2003. The teachings of each of these applications is incorporated herein by reference.

TECHNICAL FIELD

- [0002] The present invention relates generally to hydrogenation processes and fat compositions. The methods and compositions described below have particular utility in connection with hydrogenation of edible oils to form low *trans*-fatty acid fats that may be used in or as margarine, shortening, or frying fat, for example.

BACKGROUND

- [0003] A variety of relatively "hard" fat compositions, e.g., margarine, spreads, shortening, and frying fat, are formed from seed oils and vegetable oils. For example, plastic fat compositions such as margarine and low-fat spreads typically comprise an emulsion of an oil phase (typically including a liquid oil and a hard fat, which usually has been hardened) with an aqueous phase, together with various emulsifiers, stabilizers, preservatives, and flavoring agents.
- [0004] Most seed oils and vegetable oils, such as soybean oil, canola oil, corn oil, sunflower oil, palm oil, or linseed oil, contain a variety of saturated and unsaturated fatty acids. The fatty acid profiles of oils commonly vary by source, but typically include a variety of saturated fatty acids, such as palmitic acid (C16:0) and stearic acid (C18:0); some monounsaturated fatty acids such as oleic acid

(C18:1) and erucic acid (C22:1); and polyunsaturated fatty acids including linoleic acid (C18:2) and linolenic acid (C18:3). (The Cx:y designation refers to fatty acids wherein x is the number of carbon atoms and y is the number of double bonds.)

- [0005] Polyunsaturated fatty acids, particularly linolenic acid (C18:3), are known to oxidize over time with oxidation proceeding more quickly at higher temperatures such as those used in baking, frying, etc. This oxidation leads to unacceptable rancid flavors. Hence, high contents of linolenic acid can also render edible fats unstable and easily oxidized during cooking and storage, which compromises the sensory characteristics of foods cooked in or incorporating such fats. Many edible fats are hydrogenated to increase stability by reducing the amount of linolenic acid and increasing saturated and monounsaturated fatty acids. For example, the maximum desirable linolenic acid content for many commercial bakery and frying shortenings is about two weight percent of the total fatty acid content of the fat.
- [0006] Hydrogenating (mono)unsaturated fatty acids increases the saturated fatty acid content. Unduly high saturated fatty acid content in one's diet can adversely impact cardiovascular health by raising serum cholesterol levels. As a byproduct of hydrogenation, unsaturated fatty acids can be converted from their natural *cis* configuration to their *trans* isomer form. Recent studies have indicated that *trans*-fatty acids may impact cardiovascular health more negatively than saturated fatty acids do. In part due to this recent research, consumers are becoming attentive to the *trans*-fatty acid content of their diets and many consumers are beginning to prefer products with lower *trans*-fatty acid content.

#### BRIEF DESCRIPTION OF THE DRAWINGS

- [0007] Figure 1 is a schematic illustration of a catalyst activation system in accordance with one embodiment of the invention.
- [0008] Figure 2 is a schematic illustration of a hydrogenation system in accordance with another embodiment of the invention.
- [0009] Figure 3 is a graph illustrating variation of *trans*-fatty acid content as a function of Iodine Value for a soybean oil that is partially hydrogenated in accordance with standard processes or in accordance with embodiments of the invention.

[0010] Figure 4 is a graph illustrating the *trans*-fatty acid content as a function of Iodine Value for a canola oil that is partially hydrogenated in accordance with conventional hydrogenation processes as compared to select embodiments of the invention.

## DETAILED DESCRIPTION

### A. Overview

[0011] Various embodiments of the present invention provide methods for hydrogenating an unsaturated fat, e.g., an edible oil, and edible hydrogenated fat compositions. The following text discusses aspects of the invention in connection with Figures 1-4 to provide a thorough understanding of particular embodiments. A person skilled in the art will understand, however, that the invention may have additional embodiments, or that the invention may be practiced without several of the details of the embodiments shown in Figures 1 and 2.

[0012] One embodiment of the invention provides a method for hydrogenating an unsaturated fat. In accordance with this method a nickel-based catalyst is dispersed in an unsaturated edible oil. The edible oil has an initial Iodine Value and an initial fatty acid content. Hydrogen is delivered to the oil and the oil is hydrogenated at a hydrogenation temperature for a hydrogenation time to yield a partially hydrogenated fat having a modified Iodine Value and including a modified fatty acid content. The hydrogenation temperature is no greater than about 80° C, generally preferably about 70° C or less. The partially hydrogenated fat has a solid fat content of about 20-80 weight percent at 20° C. An absolute difference between the initial Iodine Value and the modified Iodine Value divided by the hydrogenation time defines an average Iodine Value change rate of no less than about 5/hour. No more than about 20 weight percent, e.g., no more than about 15 weight percent, of the modified fatty acid content comprises *trans*-fatty acids.

[0013] Another embodiment of the invention provides a method of hydrogenating an edible oil having an initial solid fat content of less than about 20 weight percent at 20° C, an initial Iodine Value, and an initial fatty acid content. This method

includes providing a catalyst composition including a fat component and a nickel-based catalyst that has been activated by heating to a first temperature. The catalyst composition is dispersed in the oil and hydrogen is delivered to the oil. The oil is hydrogenated at a second temperature to yield a partially hydrogenated fat having a modified Iodine Value and including a modified fatty acid content. The second temperature is less than the first temperature. The partially hydrogenated fat has a solid fat content of about 20-80 weight percent at 20° C. An absolute difference between the initial Iodine Value and the modified Iodine Value (dIV, discussed below) divided by the hydrogenation time defines an average Iodine Value change rate of about 6-40/hour. No more than about 20 weight percent, e.g., 15 weight percent or less, of the modified fatty acid content comprises *trans*-fatty acids.

- [0014] A partially hydrogenated fat in accordance with still another embodiment of the invention is selected from a group consisting of partially hydrogenated soy bean oil and partially hydrogenated canola oil. The partially hydrogenated fat has a solid fat content of at least about 20 weight percent at 20° C, a *trans*-fatty acid content of about 4-20 weight percent, e.g., 15 weight percent or less, and a ratio of C18 content to the *trans*-fatty acid content (C18 : TFA) of at least about one.
- [0015] Still another embodiment of the invention provides a partially hydrogenated fat, which may be selected from a group consisting of partially hydrogenated soy bean oil and partially hydrogenated canola oil, that includes a solid fat content of at least about 20 weight percent at 20°C; a *trans*-fatty acid content of about 4-20 weight percent, e.g., 15 weight percent or less; and a ratio of the solid fat content at 20°C to the *trans*-fatty acid content (SFC 20 : TFA) of at least about two.
- [0016] For ease of understanding, the following discussion is subdivided into four areas of emphasis. Section B discusses aspects of processes for activating hydrogenation catalysts and exemplary catalyst compositions including activated catalysts in accordance with selected embodiments of the invention. Section C outlines hydrogenation methods in accordance with other aspects of the invention. Section D describes edible fats in accordance with other embodiments of the invention,

and Section E discusses fat compositions that may be made with the fats of Section D (among others).

#### B. Catalyst Activation and Catalyst Compositions

- [0017] Figure 1 schematically illustrates one possible catalyst activation system 10 useful for forming an activated catalyst composition in some embodiments of the invention. The catalyst activation system 10 includes a catalyst activation vessel 20 having walls 22 defining an interior 24. A nickel-based catalyst may be delivered to the vessel interior 24 from a catalyst supply 40 via a catalyst delivery line 42. A fat component may be delivered to the vessel interior 24 from a fat supply 50 via a delivery line 52. A process gas, e.g., hydrogen gas, may be delivered to the vessel interior 24 from a process gas supply 60 via a process gas delivery line 62.
- [0018] An agitator 26 in the vessel interior 24 may enhance distribution of process gas and the nickel-based catalyst throughout the fat component during the activation process. The agitator 26 is schematically illustrated as a rotating set of paddles or blades, but those skilled in the art will recognize that any of a variety of systems may be used to distribute the process gas and the nickel-based catalyst throughout the fat component.
- [0019] The catalyst activation system 10 may also include temperature probe 34 and a heater 35 operatively coupled to the catalyst activation vessel 20 to control the temperature of the material in the vessel interior 24. The same heater 35 or separate heaters (not shown) may also be coupled to one or more of the catalyst supply 40, fat supply 50, and process gas supply 60. The catalyst activation vessel 20 may also include a pressure control 27 adapted to monitor the pressure within the vessel interior 24 and control a vent valve 29 in a vent line 28 adapted to release excess process gas and other gases (e.g., water vapor generated during the activation process) from the vessel 20. A vessel outlet 30 may be used to remove the activated catalyst from the vessel interior 24. As noted below, the outlet 30 may communicate directly with a catalyst composition supply 140 in the

hydrogenation system 100 of Figure 2 (discussed below) or send the catalyst to a storage vessel (not shown) for later use.

- [0020] The catalyst activation system 10 also includes a controller 70 adapted to control aspects of the catalyst reaction system 10. The controller 70 may be operatively coupled to one or more of the agitator 26, pressure control 27, vent valve 29, heater 35, catalyst supply 40 or delivery line 42, fat supply 50 or delivery line 52, and process gas supply 60 or delivery line 62. In one embodiment, the controller 70 comprises at least one computer having a programmable processor programmed to control operation of these components to form an activated catalyst composition.
- [0021] The nickel-based catalyst in the catalyst supply 40 may comprise any of a variety of conventional nickel-based catalysts. In one embodiment, the nickel-based catalyst comprises nickel carried on an inert support, e.g., alumina or silica. In some of these implementations, nickel may comprise about 25-100 weight percent, e.g., about 50-90 weight percent, of the nickel-based catalyst. Typically, at least some of the nickel will be present as NiO. In some embodiments, substantially all of the nickel is present as NiO, as in the case of nickel catalysts that have been calcined in air. In other embodiments, about 30-60% of the weight of the nickel is nickel metal and the balance of the weight of the nickel is contained in NiO.
- [0022] In some embodiments, substantially all of the metal carried on the inert support may comprise nickel. In other embodiments, minor amounts of copper or other metals may be added to control activity, selectivity, or other properties of the catalyst. In select implementations, the nickel-based catalyst may be at least substantially free of platinum, palladium, or ruthenium. Nickel catalysts on inert supports expected to suffice for this purpose are commercially available from Degussa AG of Frankfurt, Germany, among others.
- [0023] The fat component in the fat supply 50 may be any of a variety of fat compositions. Although the fat in the fat supply 50 may be substantially saturated, many of the embodiments of the invention will employ an unsaturated fat. As noted below, some embodiments of the invention employ catalyst compositions having relatively

low melting points. In such embodiments, the melting point of the catalyst composition produced in the catalyst activation system 10 may depend in large part on the composition of the fat in the fat supply 50.

- [0024] The fat in the fat supply 50 may comprise seed oil or vegetable oil or a blend of seed oil(s) and/or vegetable oil(s). Catalyst compositions with relatively low melting points, for example, may be formed using coconut oil or any other short-chain triacylglyceride in the fat supply 50. In other embodiments, the oil selected for the fat supply 50 may be the same type of oil that is to be hydrogenated in the hydrogenation system 100 (Figure 2, discussed below). Hence, if the catalyst composition produced in the catalyst activation system 10 is to be used to hydrogenate soybean oil, the fat supply 50 may contain or consist essentially of soybean oil. This avoids the contamination that results from using a fat in the catalyst composition different from the oil being hydrogenated with the catalyst composition.
- [0025] In the embodiment shown in Figure 1, there is a separate catalyst supply 40 and fat supply 50. In such an embodiment, the nickel-based catalyst in the catalyst supply 40 may comprise both a nickel-based catalyst as described above and a fat, e.g., a fully hardened seed oil or vegetable oil. Such nickel-based catalyst formulations are commercially available from a variety of sources, including products sold by Johnson Matthey Plc of London, UK under the trade name PRICAT. If the catalyst supply 40 includes sufficient fat to form the desired catalyst composition, the separate fat supply 50 may be omitted, essentially combining the catalyst supply 40 and the fat supply 50 into a single supply. In other embodiments, the fat supply 50 may provide a source of additional fat and both the fat-containing catalyst formulation in the catalyst supply 40 and additional fat from the fat supply 50 may be delivered to the catalyst activation vessel 20.
- [0026] If so desired, the gas in the process gas supply 60 may be substantially nitrogen-free and may consist essentially of hydrogen (e.g., commercial grade, as opposed to laboratory grade, hydrogen). In another embodiment of the invention, though, the process gas supply 60 includes a gas, e.g., a reducing gas, other than or in addition to hydrogen. For example, the process gas supply 60 may include a

supply of hydrogen gas and a separately controllable supply of nitrogen, ammonia (not shown), or other nitrogen-containing gas. In another possible embodiment, the gas in the process gas supply 60 may be a gas other than hydrogen and need not be a reducing gas, e.g., the gas may consist essentially of nitrogen and/or helium. In select embodiments, the gas may comprise a mixture of two or more of hydrogen gas, nitrogen gas, ammonia, and helium gas.

- [0027] The catalyst activation system 10 schematically illustrated in Figure 1 is a batch-type system. It is contemplated, though, that catalyst activation systems in accordance with other embodiments of the invention may activate catalyst compositions on a continuous basis.
- [0028] Some embodiments of the invention provide methods for producing an activated catalyst composition. In the following discussion, reference is made to the catalyst activation system 10 shown schematically in Figure 1. It should be understood, though, that reference to this particular system is solely for purposes of illustration and that the activation methods outlined below are not limited to the particular system shown in Figure 1 or discussed above.
- [0029] A method in accordance with one embodiment produces an activated catalyst composition by contacting a fat component with a nickel-based catalyst in the presence of a process gas at an activation temperature. The fat component may comprise oil or other fat delivered to the vessel interior 24 from the fat supply 50 via delivery line 52. In one embodiment, the fat may be delivered to the vessel interior 24 and heated to the activation temperature by the heater 35 in the vessel interior 24 before the nickel-based catalyst is added. In other embodiments, the fat component may be pre-heated before it is delivered to the vessel interior 24 and the heater 35 may simply be used to maintain the reactants in the vessel interior 24 at the desired reaction temperature.
- [0030] The controller 70 may monitor and control the pressure in the vessel interior 24 via the pressure controller 27. In one embodiment, the pressure in the vessel interior is sub-atmospheric or higher, e.g., 1-25 bar with pressures of at least two bar being useful in some configurations. In some embodiments, the pressure in the vessel interior 24 may vary depending on the state of the process. For example,

the pressure in the vessel interior 24 may be maintained below atmospheric pressure for a period of time after the fat is introduced to the vessel interior 24 to outgas air and other dissolved gases in the fat. Alternatively, or in addition to such sub-atmospheric outgassing, the fat may be purged, e.g., with nitrogen, hydrogen, or helium, to remove oxygen from the fat.

- [0031] The nickel-based catalyst may be delivered to the vessel interior 24 via the catalyst delivery line 42. In one embodiment, the nickel-based catalyst is added to a quantity of fat component in the vessel 20 when the fat component is at the desired activation temperature. In other embodiments, the nickel-based catalyst may be added prior to reaching that temperature. The agitator 26 may intermix the nickel-based catalyst with the fat component, effectively distributing the nickel-based catalyst within the fat component.
- [0032] The heater 35 may be used to maintain the temperature of the reactants in the vessel interior 24 at the desired activation temperature. If the fat in the fat supply 50 is unsaturated, contact with the nickel-based catalyst in the presence of hydrogen, for example, from the process gas supply 60 will cause an exothermic hydrogenation reaction. As a result, the reaction may proceed with no additional heat from the heater 35 and the temperature may climb during this hydrogenation process. The activation temperature is desirably at least about 100° C. It is anticipated that the reaction rate may be substantially higher at higher temperatures, which may be at least about 150°, e.g., at least about 200° C. In one exemplary embodiment, the activation temperature is about 150-200° C. The length of time during which the fat is exposed to hydrogen at the activation temperature would depend, in part, on the activation temperature. For example, the activation process may continue for five minutes or longer, e.g., 5-120 minutes, with longer times typically being employed at lower activation temperatures.
- [0033] After heating, the reactants in the vessel interior 24 may be cooled to a lower temperature. For example, the reactants may be cooled to room temperature, e.g., 20-25° C, for storage and future use or, if the reactants are to be directly added to a hydrogenation vessel (124 in Figure 2), to an intermediate temperature, e.g., 120° C. It appears that cooling these reactants in a reducing atmosphere

(e.g., a hydrogen atmosphere) or a nitrogen atmosphere can significantly improve the hydrogenation activity of the activated catalyst composition. In select embodiments of the invention, the cooling is conducted under a superatmospheric hydrogen pressure, e.g., two bar. It is anticipated that higher hydrogen pressures during cooling may further enhance the hydrogenation activity of the catalyst composition. In one particular embodiment, the reactants are cooled to an intermediate temperature close to room temperature, e.g., 35° C, under a hydrogen atmosphere, then allowed to cool from the intermediate temperature to room temperature in another atmosphere, e.g., air. In one embodiment, the intermediate temperature is less than the melting point of the fat in the catalyst composition.

- [0034] The activation process may generate gas, e.g., water vapor. This water vapor can be removed from the vessel 20, e.g., by venting the headspace through vent line 28 or via a condensation system (not shown).
- [0035] Aspects of select catalyst activation processes in accordance with the invention are illustrated in the following examples:

#### Catalyst Activation Example 1

- [0036] A first exemplary catalyst composition was formed by adding 40g of PRICAT 9920 to a round-bottom 250ml flask. The PRICAT 9920, which is commercially available from Johnson Matthey Plc, is nominally about 22 weight percent total nickel on an alumina support coated with a hardened vegetable fat as a protective medium. The hardened vegetable fat has a melting point (as measured under ISO 6321, "Melting Point in Open Capillary Tubes (Slip Point)") of about 56-69° C. The catalyst composition was heated in the flask at atmospheric pressure with a hydrogen gas flow of approximately one liter per minute to a temperature of about 200° C while stirring. The catalyst composition was stirred at that temperature and hydrogen flow rate for about 90 minutes. The hydrogen pressure was increased to about two bar and the hydrogen flow was stopped. The catalyst composition was cooled to about 20° C, yielding a solid catalyst composition.

### Catalyst Activation Example 2

- [0037] A second exemplary catalyst composition was formed using substantially the same process as that outlined in Catalyst Activation Example 1, except that about 40g of coconut oil was added to the flask with the 40g sample of PRICAT 9920. The resultant activated catalyst composition was solid at 20° C and the fat in the catalyst composition had a melting point of about 50° C.

### Catalyst Activation Example 3

- [0038] A third exemplary catalyst composition was prepared by flowing nitrogen (instead of hydrogen) through a bulk quantity of PRICAT 9920 and neutralized, bleached soybean oil to a pressure of about 2 bar. The temperature was held at about 110° C for about 120 minutes, with the nitrogen atmosphere in the reaction vessel being maintained by periodically flushing the headspace of the reaction vessel with nitrogen. The final catalyst composition was about 65 weight percent of the PRICAT 9920 nickel-based catalyst, about 22 weight percent soybean oil, and about 13 weight percent PERLITE, a commercially available filter aid.
- [0039] Once the activation process is complete, the activated catalyst composition may be removed from the vessel 20, e.g., via outlet 30. In one embodiment, the activated catalyst composition may be delivered directly from the vessel 20 to the catalyst composition supply 140 of the hydrogenation system 100, discussed below. In such an embodiment, the activated catalyst composition may be delivered to the hydrogenation system 100 at an elevated temperature, e.g., at the activation temperature or, more generally, about 100-200° C. In other embodiments, the activated catalyst composition may be allowed to cool in a separate system to a lower temperature, e.g., 20-25° C, and stored for an extended period of time. Maintaining a hydrogen atmosphere (or an atmosphere of another reducing gas) during cooling may permit longer storage times without undue loss in activity. Cooling the activated catalyst composition in a nitrogen or air atmosphere is expected to work well, though.
- [0040] It has been found, for example, that the low temperature-hydrogenation capabilities of the activated catalyst composition of some embodiments can be

maintained after storage at 20-25° C for two weeks or longer. It is anticipated that this relatively long activated shelf life will enable activated catalyst compositions in accordance with embodiments of the invention to be sold commercially to third parties for use in hydrogenation reactions. The activated catalyst composition may be stored as a relatively large block or may be divided into smaller particles to facilitate distribution of the activated catalyst composition in the feedstock to be hydrogenated.

- [0041] Other embodiments of the invention provide activated catalyst compositions. In certain embodiments, the activated catalyst compositions are prepared in accordance with the activation processes outlined above. In an embodiment of the invention, the activated catalyst composition is adapted to hydrogenate an unsaturated fatty acid component of a seed oil or vegetable oil, for example, at a temperature below that conventionally understood to be necessary for commercial hydrogenation. Although the catalyst composition may comprise only the nickel-based catalyst, activated catalyst compositions in accordance with preferred embodiments of the invention include a nickel-based catalyst dispersed in a fat matrix. The fat matrix may comprise a substantially saturated triacylglyceride, e.g., a hydrogenated fat produced using a short-chain triacylglyceride, seed oil, or vegetable oil as the fat component in the activation processes outlined above.
- [0042] The nickel-based catalyst in the activated catalyst composition is adapted to sustain, in the presence of hydrogen, a hydrogenation reaction of a composition containing polyunsaturated fatty acids at a hydrogenation temperature no greater than about 80° C, e.g., no greater than about 70° C, with 50° C or less being preferred for many applications. The nickel-based catalyst may be adapted to sustain such hydrogenation at a hydrogenation temperature of about 0-80° C, e.g., about 20-70° C, with some embodiments sustaining hydrogenation at about 30-50° C and others doing so at about 50-70° C.
- [0043] The relative proportions of the nickel-based catalyst and the fat component may vary significantly depending on such factors as the nickel content of the nickel-based catalyst and the desired total nickel content of the activated catalyst composition. In one embodiment, the total nickel content of the activated catalyst

composition is no greater than about 25 weight percent and may advantageously be 22 weight percent of the catalyst composition. (As used herein, the term "total nickel content" refers to the total weight of nickel in the nickel-based catalyst or the catalyst composition. For example, if some of the nickel in the nickel-based catalyst were present as NiO, the total nickel content would include the weight of the nickel in the NiO, as well.) Catalyst compositions having total nickel contents as low as about one weight percent may be employed in some circumstances. Preferably, though, the total nickel content in the catalyst composition is higher than that. Hence, in one embodiment, the total nickel content is about 2-50 weight percent, e.g., between about 2 and about 35 weight percent, with a range of about 2-25 weight percent being useful for many embodiments.

- [0044] The preceding discussion focuses on catalyst compositions comprising nickel-based catalysts. The industry-proven selectivity of many nickel-based catalysts is believed to be particularly useful in connection with certain types of feedstocks. It is anticipated, though, that the processes outlined above may enhance the catalytic activity of other hydrogenation catalysts. For example, it is anticipated that the catalytic activity of platinum in hydrogenation reactions may be increased using aspects of the process outlined above. This may enable hydrogenation using lower concentrations of the catalyst, at lower temperatures, or at higher rates than may otherwise be achieved.
- [0045] Activated catalyst compositions in accordance with embodiments of the invention can be used advantageously in a variety of hydrogenation reactions. For example, activated catalyst compositions in accordance with aspects of the invention have particular utility in hydrogenation of seed oils and vegetable oils. As explained below, these activated catalyst compositions can hydrogenate such oils at temperatures lower than conventionally understood to be necessary for hydrogenation at commercially acceptable rates, which can limit formation of *trans*-fatty acids.

### C. Methods for Hydrogenating Edible Oils

- [0046] Other embodiments of the invention provide systems and methods for hydrogenating unsaturated feedstocks at reduced temperatures. Figure 2 schematically illustrates a hydrogenation system 100 that may be used in hydrogenating a feedstock in accordance with certain embodiments of the invention. This hydrogenation system 100 includes a hydrogenation vessel 120 including a wall 122 defining a hydrogenation vessel interior 124. A pressure control 127 may be used to monitor pressure within the hydrogenation vessel 120 and control a vent valve 129 in a vent line 128 adapted to release excess hydrogen gas, water vapor, and other gases from the vessel 120. In one embodiment, the vent line 128 may be coupled to a vacuum source 131 to further facilitate pressure control. Alternatively, the vacuum source 131 may communicate with the vessel interior 124 via a separate vacuum line (not shown). An agitator 126, which may be analogous to the agitator 26 of Figure 1 described above, may be disposed in the hydrogenation vessel interior 124 to mix the reactants within the vessel 120.
- [0047] The hydrogenated product may be removed from the hydrogenation vessel 120 via an outlet 130. In the catalyst activation system 10 of Figure 1, the nickel-based catalyst was intended to remain within the catalyst composition exiting the activation vessel 20 via the outlet 30. In most intended applications of the hydrogenated product, it may be desirable to remove the nickel-based catalyst from the final hydrogenated product. As is known in the art, a filter 132 may be used to remove the nickel-based catalyst from the hydrogenated product exiting via the outlet 130. In some embodiments, the nickel-based catalyst removed by the filter 132 may be reused, either directly or after further processing. Such further processing may comprise, for example, repeating the activation process outlined above to reactivate the nickel-based catalyst.
- [0048] The hydrogenation system 100 also includes a temperature probe 134 and a thermal control 135 that may be operatively coupled to the hydrogenation vessel 120. In one embodiment, the thermal control 135 comprises a heat source, e.g., a

radiative or conductive heater. In other embodiments, the thermal control 135 may instead be used to cool the contents of the hydrogenation vessel 120, e.g., to prevent the contents of the hydrogenation vessel 120 from exceeding a maximum desired temperature during the exothermic hydrogenation reaction conducted in the vessel 120.

- [0049] A controller 170 may be used to control operation of the hydrogenation system 100. The controller 170 may be operatively coupled to one or more of the agitator 126, pressure control 127, vent valve 129, vacuum source 131, thermal control 135, catalyst composition supply 140 (discussed below), feedstock supply 150 (discussed below), and hydrogen supply 160 (also discussed below). The controller 170, like the controller 70 of Figure 1, may comprise at least one computer having a programmable processor. The programmable processor may be programmed to control operation of the various components of the hydrogenation system 100 to appropriately hydrogenate the feedstock.
- [0050] A catalyst composition may be delivered from a catalyst composition supply 140 to the hydrogenation vessel interior 124 via a delivery line 142. The catalyst composition in the catalyst composition supply 140 desirably comprises an activated nickel-based catalyst composition capable of sustaining a hydrogenation reaction at a suitably low hydrogenation temperature. In many embodiments of the invention, the catalyst composition may comprise an activated catalyst composition such as that described above, including a nickel-based catalyst and a fat.
- [0051] An unsaturated fat may be delivered to the interior 124 of the hydrogenation vessel 120 via a delivery line 152 from a fat supply 150. A wide variety of unsaturated fats may be employed to yield different hydrogenated products. The hydrogenation system 100 and the activated catalyst composition in the supply 140 have particular utility in connection with hydrogenating edible oils of all types. The edible oils utilized in some embodiments of the invention are liquid oil from seed, vegetable, or marine sources and include, but are not limited to, soybean oil, canola oil, corn oil, high oleic sunflower oil, linseed oil, cottonseed oil, and fish oil. Other embodiments may utilize semi-solid or solid oils or fats from seed,

vegetable, or marine sources and include, but are not limited to, palm oil, coconut oil, cocoa butter, tallow, marine fats, and the like. If so desired, the unsaturated fat feedstock can be a blend of seed oil(s), vegetable oil(s), and/or marine oil(s). In select embodiments, the feedstock comprises a neutralized, bleached seed or vegetable oil, though some applications may use deodorized oils. In addition, the feedstock need not be triglyceride oil and may instead be a mono- or diglyceride or even a free or esterified fatty acid.

- [0052] The hydrogenation system 100 also includes a hydrogen supply 160 adapted to deliver hydrogen to the reactants in the hydrogenation vessel 120 via a delivery line 162. In one embodiment, the hydrogen supply 160 comprises hydrogen gas, e.g., a commercial hydrogen gas consisting essentially of hydrogen. In other embodiments, the hydrogen supply 160 may include gases other than hydrogen. These other gases may be provided in a separate gas supply (not shown). As in the case of the process gas supply 60 of Figure 1, discussed above, the hydrogen supply 160 may, for example, include a separate supply of ammonia or other nitrogen-containing compound, which may enhance selectivity of the hydrogenation reaction. If an edible fat composition is to be produced in the hydrogenation system 100, though, it may be advantageous to omit use of ammonia or other nitrogen-containing compounds.
- [0053] Figure 2 schematically illustrates a batch-type hydrogenation system 100. In other embodiments of the invention, an alternative hydrogenation system may be employed to hydrogenate the unsaturated fat feedstock on a continuous basis. For example, a nickel-based catalyst may be activated in a fixed or fluidized bed and the unsaturated fat feedstock and hydrogen gas may be passed through this bed of activated catalyst.
- [0054] Other embodiments of the invention provide methods of hydrogenating an unsaturated fat. The following discussion of such methods refers to the hydrogenation system 100 of Figure 2. It should be recognized, however, that methods in accordance with the invention may be conducted using any suitable equipment and the invention is not limited to the specific apparatus shown in Figures 1 and 2 and discussed above.

- [0055] In accordance with an embodiment of the invention, an unsaturated fat feedstock is contacted with a nickel-based catalyst in the presence of hydrogen. The relative proportions of the feedstock and the catalyst composition added to the hydrogenation vessel 120 will depend, at least in part, on the nickel content of the catalyst composition. In one embodiment, the total nickel content of the combined catalyst composition and feedstock is no greater than 1 weight percent, e.g., 0.01-1 weight percent. In one embodiment found to work well, the total nickel content is about 0.1-0.3 weight percent of the combined catalyst composition and feedstock. The nickel-based catalyst may be dispersed within the feedstock, e.g., by activating the agitator 126. Although it may be possible to utilize catalysts in addition to the nickel-based catalyst from the activated catalyst composition, it is anticipated that, in most embodiments, the activated catalyst composition will be substantially the only catalyst source during the hydrogenation of the feedstock.
- [0056] As noted above, the activated catalyst composition may comprise a nickel-based catalyst dispersed in a fat matrix, e.g., a fully saturated fat component. If the catalyst composition is at a temperature below the melting point of the fat matrix, the fat matrix will limit interaction between the nickel-based catalyst and the feedstock in the hydrogenation vessel 120. If the catalyst composition is employed above its melting point, though, the melted fat matrix may be mixed with the bulk of the feedstock, allowing the nickel-based catalyst to intimately mix with the feedstock. Accordingly, in one embodiment of the invention, the fat component of the catalyst composition has a melting point that is no higher than the temperature at which hydrogenation is to be conducted in the hydrogenation vessel 120, e.g., no higher than about 50° C. This melting point may be determined in accordance with ISO 6321, mentioned above.
- [0057] In other embodiments, it may be less desirable or less practical to employ a catalyst composition in which the fat component has a melting point lower than the intended hydrogenation temperature. To ensure adequate commingling of the nickel-based catalyst and the feedstock, it is preferable that such a catalyst composition be heated to a temperature at least as great as its melting point. Advantageously, this may be done prior to mixing the catalyst composition with the

feedstock. Hence, in one embodiment the catalyst composition may be delivered from the catalyst composition supply 140 to the hydrogenation vessel 120 at a temperature greater than the intended hydrogenation temperature. In such an embodiment, the catalyst composition supply 140 and/or delivery line 142 may include a heater to elevate the temperature of the catalyst composition above the melting point of the fat component. This heated catalyst composition may then be added to a supply of the feedstock in the hydrogenation vessel 120. The feedstock in the hydrogenation vessel 120 may be at a temperature below the intended hydrogenation temperature and the addition of the warmer catalyst composition can elevate the combined temperature to the intended hydrogenation temperature. If further heating is needed to begin the hydrogenation process, the thermal control 135 may heat the contents of the hydrogenation vessel 120.

- [0058] Alternatively, the catalyst composition may be heated in the hydrogenation vessel 120 to a temperature at least as great as its melting point prior to the addition of the feedstock. In one particular embodiment, the nickel-based catalyst may be activated in the same reaction vessel that is used to carry out the hydrogenation reaction. Hence, in the context of Figures 1 and 2, the feedstock supply 150 and the filter 132 may be added to the catalyst activation system 10 and the feedstock may be added to the catalyst activation vessel 20 upon completion of the catalyst activation process. The activated catalyst composition may be at a temperature substantially higher than the intended hydrogenation temperature, but addition of the feedstock at a temperature below the intended hydrogenation temperature will cool the activated catalyst composition.
- [0059] In one embodiment, hydrogen is introduced to the feedstock in the hydrogenation vessel 120 before addition of the activated catalyst composition. For example, a batch of the feedstock to be hydrogenated may be added to the hydrogenation vessel 120, the pressure control 127 may reduce pressure in the hydrogenation vessel 120 via vent line 128, and a flow of hydrogen from the hydrogen supply 160 may be initiated. This will help to de-aerate the feedstock and create a reducing environment in the reaction vessel before the activated catalyst composition is added to the reaction vessel. De-aerating and introducing hydrogen in this fashion

is anticipated to maintain higher hydrogenation activity in the nickel-based catalyst and limit *trans*-fatty acid formation. This may also help limit the impact of some impurities in the feedstock, some of which (e.g., sulfur) are expected to have a negative impact on the continued catalytic activity of the nickel-based catalyst over time.

- [0060] During hydrogenation, the pressure control 127 may be used to control the pressure in the hydrogenation vessel 120. As is known in the art, maintaining superatmospheric pressures in the hydrogenation vessel 120 can increase solubility of the hydrogen in an oil feedstock, facilitating hydrogenation. Appropriate pressures may depend, at least in part, on the nature of the feedstock. When hydrogenating common seed oils or vegetable oils, for example, the pressure in the hydrogenation vessel 120 likely will remain less than 100 bars absolute (bar-a), e.g., 50 bar-a or less. In one embodiment, the pressure in the hydrogenation vessel 120 during hydrogenation is about 1-30 bar-a.
- [0061] A solvent may be added to reduce viscosity of the feedstock, promoting effective introduction and transport of hydrogen-containing gas. That is not believed to be necessary for hydrogenating most seed oils, vegetable oils, or marine oils, though, and may be disadvantageous when producing an edible fat composition for food applications. In one embodiment, therefore, the feedstock is a seed oil, vegetable oil, or marine oil and the hydrogenation process is conducted substantially solvent-free.
- [0062] Suitable hydrogenation temperatures will depend in part on the nature of the feedstock being hydrogenated (e.g., melting point) and the nature of the fat composition being produced. In one embodiment the hydrogenation temperature is no greater than about 80° C, with initial temperatures of 50° C or less being advantageous for hydrogenating seed oils, vegetable oils, or marine oils to produce fats for use in margarine, shortening, or the like with a low *trans*-fatty acid content.
- [0063] As noted above, hydrogenation is an exothermic reaction. In some embodiments, the hydrogenation is initiated and sustained for a time at a hydrogenation temperature in one of the stated temperature ranges, but may increase beyond

that range during hydrogenation. For example, the hydrogenation reaction may be initiated at a temperature not greater than about 50° C and the temperature may be allowed to increase, e.g., about 10-30° C, during the course of the hydrogenation reaction. If so desired, the hydrogenation temperature is maintained within one of the above-stated temperature ranges (e.g., no greater than about 70° C) during the entire hydrogenation process. This may be accomplished, for example, by controlling the flow rate of hydrogen from the hydrogen supply 160 or by cooling the vessel with the thermal control 135.

- [0064] One measure for characterizing an average number of double bonds present in the fatty acids of an oil is the Iodine Value, which is typically determined by the Wijs method (A.O.C.S. Method Cd 1-25). For example, soybean oil typically has an Iodine Value of about 125-135 and canola oil typically has an Iodine Value of about 97-108. Because hydrogenation saturates the double bonds in the triglycerides, a decrease in Iodine Value will serve as a reasonable proxy of a measurement of the degree of hydrogenation. As a corollary, therefore, the rate of change of the Iodine Value for an oil can serve as a proxy for the rate of hydrogenation.
- [0065] The rate of hydrogenation, and the rate at which the Iodine Value changes, may decrease as the number of double bonds in the oil decreases. An average Iodine Value change rate may be determined by determining the absolute difference between the initial Iodine Value of the oil prior to hydrogenation and the modified Iodine Value of the hydrogenated oil, and dividing that difference by the hydrogenation time. Average Iodine Value change rates of less than about 5/hour correspond to hydrogenation rates that are commercially unacceptable for most conventional edible hydrogenated fats. Accordingly, in embodiments of the invention employed in manufacturing edible fat compositions, for example, the average Iodine Value change rate is desirably no less than about 5/hour. Average Iodine Value change rates of about 6-60/hour are expected to suffice for many commercial hydrogenation processes of edible fats, with average Iodine Value change rates of about 10-40/hour, e.g., about 20/hour, being typical for many embodiments of the invention.

[0066] The hydrogenation system 100 schematically illustrated in Figure 2 is a batch-type system. It is contemplated, though, that hydrogenation systems in accordance with other embodiments of the invention may hydrogenate fats on a continuous basis.

D. Edible, Partially Hydrogenated Fats

[0067] Edible, partially hydrogenated fat compositions in accordance with another embodiment may comprise a partially hydrogenated oil, e.g., a partially hydrogenated seed oil, vegetable oil, or marine oil, and, optionally, an aqueous component. In select embodiments, the fat in these edible fat compositions may be formed by the hydrogenation processes outlined above.

[0068] One of the purposes of hydrogenating an oil is to improve its stability, e.g., in air. Reducing the C18:3 content of oils that include C18:3, e.g., soybean oil or canola oil, can significantly improve stability of fats and fat compositions made with the oil. Some other oils, e.g., sunflower oil, have relatively little C18:3, but may include C18:2, another polyunsaturated fatty acid. A number of industry-accepted tests determine the oxidative stability of a fat by measuring the "induction period" on a RANCIMAT, sold commercially by Metrohm Ltd. of Herisau, Switzerland. One exemplary RANCIMAT test is ISO/DIS 6886.2. Refined soybean and sunflower oils typically have induction periods at 120° C (referred to below as "R 120") on the order of about 3 hours, with refined canola oil having a somewhat longer induction time of about 4 hours at the same temperature. Hydrogenating an oil in accordance with embodiments of the invention may significantly increase the induction period of the hydrogenated fat composition. In some embodiments of the invention, for example, the hydrogenation process desirably increases the induction period at least four-fold. In select examples, the induction period at 120° C is about 20-75 hours or more, which is as much as twenty-five times the standard 3-4 hour induction times for soybean, canola, and sunflower oils, for example.

[0069] Conventional wisdom dictates that seed oils or vegetable oils such as soybean or canola oils must be hydrogenated at temperatures of 100° C or higher to achieve

commercially acceptable hydrogenation. Conventional wisdom also suggests that the lowest temperature at which a nickel-based catalyst will initiate hydrogenation is about 80° C As noted above, though, hydrogenating seed oils or vegetable oils at temperatures of 100° C or greater will increase the *trans*-fatty acid content in a resultant fat to relatively high levels, typically greater than 25 weight percent of the fatty acid, with 30-45 weight percent being commonplace for partially hydrogenated fats used as a major component of margarine or shortening.

- [0070] *Trans*-fatty acid content (TFA) as used herein is based upon the typical analytical methodology for analyzing the fatty acid profile of fats and oils. TFA content is presented as a weight percentage of *trans*-fatty acids relative to the fat's overall content of fatty acids. Therefore, if an oil sample contains only 20 weight percent fatty acids but half of these fatty acids existed in the *trans*-configuration, the TFA content would be represented herein as 50 weight percent.
- [0071] Increasingly, health-conscious consumers are looking for fat compositions with lower *trans* content and some industry standards are expected to require *trans*-fatty acid contents for margarine fats of no greater than about 5 weight percent and no greater than about 15 weight percent for shortening. The processes of some embodiments of the invention permit manufacture of partially hydrogenated edible fats having a TFA content of less than about 20 weight percent, preferably less than about 15 weight percent. In other embodiments, the TFA content is between about 4 and about 20 weight percent, with a range of about 5-10 weight percent being desirable for many embodiments.
- [0072] Hydrogenating seed oils or vegetable oils with an activated catalyst composition in accordance with select embodiments of the invention yields partially hydrogenated fats with reduced *trans*-fatty acid levels. In one embodiment, the unsaturated fat feedstock comprises an oil in which 6% or more of the fatty acid content is C18:3. For example, soybean oils typically have C18:3 contents on the order of about 7%, and canola oils often have C18:3 contents of 9% or higher. Hydrogenating such a feedstock with an activated catalyst composition at a reduced hydrogenation temperature in accordance with an embodiment of the invention, e.g., 50° C or less, can yield a hydrogenated fat that has a solid fat content (explained below) of

about 20-80 weight percent at typical storage temperatures of about 20° C in which no more than about one weight percent (preferably no more than about 0.1 weight percent) of the fatty acid content is C18:3 and no more than about 20 weight percent (preferably no more than about 15 weight percent) of the fatty acid content is *trans*-fatty acids.

- [0073] Solid fat content will affect many aspects of a fat or a fat composition made therewith. For example, the solid fat content at anticipated use and storage temperatures, e.g., about 10-20° C, can affect physical properties and/or stability of an emulsion. At higher temperatures, e.g., 30°-40° C, the solid fat content can affect organoleptic properties such as mouth feel. One known measurement of solid fat content at a particular temperature, method NEN-EN-ISO 8292, employs nuclear magnetic resonance. A fat in one exemplary embodiment is at least semi-solid at 25° C and has a solid fat content measured at 20° C (SFC 20) of no less than about 10 weight percent and a solid fat content measured at 30° C (SFC 30) of no greater than about 3 weight percent. Another embodiment provides a fat that is a pumpable solid at 25° C, has a SFC 20 of no less than about 25 weight percent and a SFC 30 of no greater than about 15 weight percent.
- [0074] Some commercially available margarines and shortenings employ fats having a *trans*-fatty acid content of less than 15 weight percent, with some having a *trans*-fatty acid content of two weight percent or less. These products are typically formed by blending and/or interesterification of a fully hydrogenated oil with an unhydrogenated oil. For example, U.S. Patent 5,407,695 (the entirety of which is incorporated herein by reference) proposes blending a substantially fully hydrogenated oil, i.e., an oil in which all of the fatty acids have been substantially fully saturated, with an unhydrogenated oil, e.g., in a 50/50 blend. European Patent Specification EP 0 792 107 B1 (the entirety of which is incorporated herein by reference) suggests a fat blend for margarines that is made by fully hydrogenating a quantity of an oil, e.g., soybean oil, and interesterifying that with an unhydrogenated oil, which may be the same type of oil, e.g., unhydrogenated soybean oil. In both of these approaches, the fully hydrogenated product will not include double bonds, so it will not include any *trans* isomers. Hence, the only

*trans*-fatty acid content in such a blend typically would come from the unhydrogenated oil.

- [0075] Although fully hydrogenated+liquid ("FH+L") blends (namely, blends in which at least one of the blended and/or interesterified fats is fully hydrogenated and at least one of the blended and/or interesterified fats is at least pumpable) can have relatively low C18:3 and *trans*-fatty acid content, there are some drawbacks. For example, FH+L blends tend to have relatively low stability at elevated temperatures, e.g., at baking temperatures. Whereas a shortening made using conventional partially hydrogenated soybean oil may have a R 120 induction period of about 50 hours, some blended shortenings have R 120 induction periods of less than 20 hours, e.g., 10 hours. Initial review suggests that a FH+L blend employing about 60 weight percent standard hardened soybean oil with a melting point of 45° C and the balance unhydrogenated canola oils, for example, will have induction times on the order of 12 hours. Many commercial baking applications call for a shortening with a minimum R 120 induction period of 20 hours or longer, limiting the market acceptance of most blends. As noted above, embodiments of the invention have induction times of 20 hours or longer, with induction times of about 40 hours, e.g., about 50 hours, being achieved in some embodiments.
- [0076] Another drawback of conventional FH+L blends is that their solid fat contents do not vary much with temperature. When manufacturing baked goods such as pastries, for example, it may be desirable to have a relatively low solid fat content, e.g. no greater than about 15 weight percent, at about 35-40° C to avoid a greasy mouth feel when eaten. Typical FH+L blends with a SFC 20 of at least about 40 weight percent may include appreciable solid fats at 40° C, e.g., a FH+L blend with 40 weight percent fully hydrogenated soy fat may have a SFC 40 of 35 weight percent and a FH+L blend including about 60 weight percent fully hydrogenated soy fat may have a SFC 40 or 50 weight percent or more. Embodiments of the present invention having a SFC 20 of about 40, however, may yield a fat having a SFC 40 of about 10 weight percent or less.
- [0077] The ratio of unsaturated *cis*-C18:y fatty acids (i.e., C18:1, C18:2, and C18:3) to the corresponding *trans*-C18:y fatty acids in a partially hydrogenated oil is an

indication of the *trans*-selectivity of the hydrogenation process. More particularly, a higher ratio of unsaturated *cis*-C18:y fatty acid content to *trans*-C18:y fatty acid content suggests a lower likelihood of *trans* isomerization of an adsorbed carbon-carbon double bond at the catalyst surface. Higher ratios of unsaturated *cis*-fatty acids to *trans*-fatty acids, therefore, are preferred for many edible fats.

- [0078] As noted above, *trans*-fatty acids may impact cardiovascular health more deleteriously than saturated fats. The ratio of saturated C18 fatty acids to *trans*-fatty acids in a partially hydrogenated fat, therefore, can suggest health-related aspects of the fat. A higher ratio of C18 to *trans*-fatty acid can be considered more desirable, at least as long as the C18 content is not unduly high. A number of edible oils, e.g., soybean oil and canola oil, have C18 contents of 6 weight percent or less, e.g., about 4 weight percent or less, prior to hydrogenation. For example, one exemplary deodorized, bleached soybean oil has a C18 content of about 4 weight percent and one exemplary deodorized, bleached canola oil contains about two weight percent C18. Hydrogenation tends to increase C18 levels and conventional processes can yield C18 levels of 7 weight percent or higher for fats having a SFC 20 of about 30 weight percent. *Trans*-fatty acid content also increases during hydrogenation, though, and conventional processes yield at least about 36 weight percent *trans*-fatty acid in such a fat. As a result, conventional partially hydrogenated fat typically has more *trans*-fatty acid than C18, yielding a ratio of C18 to *trans*-fatty acid less than one, most commonly 0.7 or less.
- [0079] The ratio of unsaturated *cis*-C18:y fatty acids (i.e., C18:1, C18:2, and C18:3) to the corresponding *trans*-C18:y fatty acids in a partially hydrogenated oil is an indication of the *trans*-selectivity of the hydrogenation process. More particularly, a higher ratio of unsaturated *cis*-C18:y fatty acid content to *trans*-C18:y fatty acid content suggests a lower likelihood of *trans* isomerization of an adsorbed carbon-carbon double bond at the catalyst surface. Higher ratios of unsaturated *cis*-fatty acids to *trans*-fatty acids, therefore, are preferred in many edible fats.
- [0080] One useful embodiment of the invention provides a partially hydrogenated edible fat (e.g., soy or canola oil) that has a solid fat content of about 20-80 weight percent at about 20° C; has a C18:3 content of about one weight percent or less,

e.g., no greater than about 0.1 weight percent; and includes no more than about 20 weight percent, e.g., no more than about 15 weight percent, of *trans*-fatty acids. This fat may also have a ratio of unsaturated *cis*-C18:y fatty acids to *trans*-C18:y fatty acids (abbreviated below as CFA : TFA) of at least about two, with a ratio of about 3 or greater, e.g., about 4 or more, being desirable. One particular embodiment has a CFA : TFA ratio of at least about 6. Typically, conventional partially hydrogenated edible soybean and canola fats having similar rheology and C18:3 content will have CFA : TFA ratios of less than 2, with some being less than one.

- [0081] As noted previously, FH+L blends tend to be less stable than similar partially hydrogenated fats. Very high CFA : TFA ratios are commonly associated with FH+L blends, which typically have CFA : TFA ratios of at least about 15, often 25 or higher. Hence, the CFA : TFA ratio in select embodiments of the invention is no greater than about 13, e.g., about 10 or less.
- [0082] Another embodiment of the invention provides a partially hydrogenated edible fat that has a SFC 20 of at least about 20 weight percent, desirably 25 weight percent or higher, and includes no more than about 20 weight percent, e.g., no more than about 15 weight percent, of *trans*-fatty acids. This fat may also have a ratio of saturated C18 to *trans*-C18:y fatty acid (abbreviated below as C18 : TFA) of at least about one, e.g., about two or higher. In some embodiments of the invention, the C18 : TFA ratio is at least about 2.5, e.g., 4.0 or greater. Some particular embodiments have a C18 : TFA ratio of 5 or higher. This is in contrast to conventionally hydrogenated soybean and canola fats with SFC 20 of 20 weight percent or higher, which typically have a C18 : TFA ratio of less than 0.5, with ratios on the order of about 0.3 or less being commonplace. For example, the conventionally hydrogenated soybean fat S180 with SFC 20 of 26 weight percent had a C18 : TFA ratio of about 0.15 (See Table A2). Conventional partially hydrogenated canola fats with SFC 20 of at least 20 weight percent typically have C18 : TFA ratios below 0.25. Sample C180, for example, had a C18: TFA ratio of about 0.21 at a SFC 20 of 24 (See Table B2). Although other oils may be used, some particularly useful implementations of this embodiment comprise partially

hydrogenated soybean fat, partially hydrogenated canola fat, or a partially hydrogenated blend of soybean and canola fats.

- [0083] FH+L blends commonly have C18 : TFA ratios of at least about 25 and may be 30 or higher. Such blends are generally considered less stable than partially hydrogenated oils. Hence, the C18 : TFA ratio in select embodiments of the invention is no greater than about 10, with C18 : TFA ratios of about 8 or less being useful for a number of applications.
- [0084] The solid fat content is one of the most commonly specified parameters of a partially hydrogenated fat to be used either alone (e.g., as a shortening) or as a component of a fat composition (e.g., a component of margarine). As noted above, embodiments of the invention have a solid fat content at 20° C (SFC 20) of about 20-80 weight percent, desirably about 30-70 weight percent. Increasing the solid fat content from the lower end of this range typically requires more thorough hydrogenation, which, in turn, can increase the *trans*-fatty acid content of most conventionally hydrogenated oils. Accordingly, a ratio of the solid fat content at a particular temperature to the *trans*-fatty acid content is indicative of the efficiency, from a TFA content perspective, of achieving a desired solid fat content. For example, a relatively high ratio of the SFC 20 to the TFA content suggests that a particular solid fat content target may be achieved while keeping the TFA content within acceptable levels. The same can be said of the solid fat content at other temperatures, e.g., the ratio of the SFC 30 to the TFA content (referred to below as SFC 30 : TFA). Comparing these ratios at two different temperatures can be particularly instructive for defining the rheology of a low *trans*-fatty acid fat.
- [0085] Embodiments of the present invention have a SFC 20 : TFA, of at least about two, e.g., at least about 4, for partially hydrogenated fats having a SFC 20 of at least about 25. In select embodiments, particularly those including a higher solid fat content, e.g., greater than 40 weight percent solid fats at 20°C, the SFC 20 : TFA ratio may be 5 or higher with select embodiments having a minimum SFC 20 : TFA ratio of about 6. In some useful embodiments in the invention, the fat has a SFC 20 of between about 25 and about 40 weight percent and has a SFC 20 : TFA ratio of at least about two, with select embodiments having a minimum SFC 20 :

TFA ratio of 3, e.g., 4 or higher, optionally 5 or higher. In other embodiments of the invention in which the fat has a SFC 20 of about 40-60 weight percent, the SFC : TFA ratio is at least about 4, e.g., 5 or higher. These numbers are particularly well suited to partially hydrogenated soy fats and canola fats, for example.

- [0086] Further embodiments of the invention have a SFC 30 : TFA ratio of at least about one, preferably two or higher, for a fat having a SFC 20 of at least about 10 weight percent. In select embodiments, the SFC 30 : TFA ratio is at least about 2.5, e.g., 3 or higher, for a partially hydrogenated fat, e.g., a partially hydrogenated soy fat or canola fat, having a SFC 30 of about 10-45 weight percent.
- [0087] The fatty acid profiles of fats of the invention will depend to a significant extent on the nature of the oil being hydrogenated. The following will summarize some exemplary embodiments of the invention using specific starting oils. In each of these particular embodiments, the partially hydrogenated fat has a solid fat content of about 20-80 weight percent at about 20° C.
- [0088] **Soybean Oil:** The partially hydrogenated fat in one exemplary embodiment of the invention comprises a partially hydrogenated soy fat with a TFA content of about 4-20 weight percent, preferably no more than about 15 weight percent, e.g., about 5-10 weight percent. In one implementation of this embodiment, the partially hydrogenated soy fat has a SFC 20 of about 25-60 weight percent and a SFC 20 : TFA ratio of at least about two, preferably about 4 or higher, e.g., 5 or higher and optionally at least about 6. In another implementation, a partially hydrogenated soy fat having a SFC 30 of about 10-45 may have a SFC 30 : TFA ratio of at least one, desirably about two or higher, e.g., 2.5 or higher and optionally 3 or higher. Another adaptation of this embodiment provides a soy fat that has been partially hydrogenated to have a SFC 20 of at least about 25 weight percent such that the ratio of the absolute value of the decrease in Iodine Value to the *trans*-fatty acid content on a weight percent basis (dIV : TFA) is at least about 5, e.g., 7.5 or higher, with select embodiments having a dIV : TFA ratio of about 9 or higher. In another implementation of this embodiment, the CFA: TFA ratio is at least about two, e.g., 3 or higher. In select implementations, this ratio is at least about 4, e.g.,

5 or higher. In some embodiments, the CFA : TFA ratio may also be no greater than about 13, e.g., about 10 or less. In another implementation, the C18 : TFA ratio is at least about one, e.g., at least about two, with select embodiments having a C18 : TFA ratio of 3 or greater, e.g., about 4 or greater. If so desired, the C18 : TFA ratio may also be no greater than about 10, e.g., about 8 or less. Embodiments having a R 120 induction period of at least about 25 hours, preferably about 40 hours or longer, may be particularly utile, e.g., as a frying or bakery shortening.

[0089] **Canola Oil:** Another exemplary embodiment of the invention provides a partially hydrogenated canola fat with a TFA content of about 4-20 weight percent, preferably no more than about 15 weight percent, e.g., about 5-10 weight percent. In one implementation of this embodiment, the partially hydrogenated canola fat has a SFC 20 of about 25-60 weight percent and a SFC 20 : TFA ratio of at least about two, e.g., at least about 3, desirably at least about 4 and optionally about 6 or greater. One other adaptation of the embodiment provides a partially hydrogenated canola fat with a SFC 30 of about 10-45 weight percent and a SFC 30 : TFA ratio of at least about two, e.g., at least about 2.5, with select embodiments having a SFC 30 : TFA ratio of 5 or greater. In another adaptation of this embodiment, the partially hydrogenated canola fat has a SFC 20 of about 25-60 and a dIV : TFA of at least about 4, e.g., 5 or higher, with select embodiments having a dIV : TFA ratio of at least about 8, e.g., 10 or higher. The CFA : TFA ratio is at least about 3, e.g., 4 or higher. In select implementations, this ratio is at least about 5, with CFA : TFA ratios of 7 or higher deemed particularly useful. If so desired, the CFA : TFA ratio may also be no greater than about 15, e.g., about 12 or less. In another implementation, the C18 : TFA ratio is at least about one, e.g., at least about two, with select embodiments having a C18 : TFA ratio of 3 or greater, e.g., 4 or greater. If so desired, the C18 : TFA ratio may also be no greater than about 15, e.g., about 10 or less. Embodiments having a R 120 induction period of at least about 25 hours, preferably about 40 hours or longer may be particularly utile, e.g., as a frying shortening.

- [0090] **Sunflower Oil:** Partially hydrogenated sunflower fat in accordance with some embodiments of the invention have fatty acid profiles that depend on whether the oil is a "conventional" or "high-oleic" variety. As used herein, a conventional sunflower oil has a C18:1 (oleic acid) content less than 77 weight percent prior to hydrogenation; high-oleic sunflower oil has a C18:1 content of at least about 77 weight percent prior to hydrogenation. A sunflower fat made by partially hydrogenating a conventional sunflower oil may have a TFA content of about 4-20 weight percent, preferably no more than about 15 weight percent, e.g., about 5-10 weight percent. In an alternative embodiment that employs a high-oleic sunflower oil, the resultant partially hydrogenated sunflower fat has a TFA content of about 4-15 weight percent, e.g., no more than about 10 weight percent. The partially hydrogenated sunflower fat may have a SFC 20 of about 20-80 weight percent and a SFC 20 : TFA ratio of at least about two and it may also have a SFC 30 of about 10-45 weight percent and a SFC 30 : TFA ratio of at least about two. In another adaptation, the partially hydrogenated sunflower fat has a SFC 20 of about 20-80 weight percent and a dIV : TFA ratio of at least about 5, e.g., about 8 or higher, with select embodiments having a dIV : TFA ratio of 10 or higher. The CFA : TFA ratio may be at least about 4, e.g., 5 or higher, and may optionally be no greater than about 20, e.g., no more than about 15. In another aspect, a partially hydrogenated sunflower fat in accordance with an embodiment of the invention may have a C18 : TFA ratio and is at least about one, e.g., at least about two, with some particular implementations having a C18 : TFA ratio of 3 or greater. If so desired, the C18 : TFA ratio may also be no greater than about 20, e.g., about 15 or less. Some embodiments of the invention also provide a partially hydrogenated sunflower fat that has a R 120 induction period of 25 hours or longer, e.g., at least about 40 hours.
- [0091] **Palmolein:** A partially hydrogenated palmolein fat in other embodiments of the invention has SFC 20 of 40 weight percent or more and contains no more than about 10 weight percent, e.g., no more than about 5 weight percent *trans*-fatty acids. In one implementation of this embodiment, The SFC 20 : TFA ratio is at least about 4, e.g., 8 or higher, and preferably at least about 10. Other

embodiments provide partially hydrogenated palmolein fat with a SFC 20 of 40 weight percent or more and a dIV : TFA ratio of at least about two, e.g., 4 or higher. The CFA : TFA ratio may be at least about two and, optionally, no greater than about 15. The C18 : TFA ratio of a partially hydrogenated palmolein fat in another embodiment is at least about two, e.g., 3 or higher, and may optionally be no greater than about 20, e.g., about 15 or less. Other embodiments of the invention provide a partially hydrogenated palmolein fat with a R 120 induction period of at least about 25 hours, e.g., 40 hours or longer.

- [0092] **Palmoil:** A further embodiment of the invention provides a partially hydrogenated palmoil fat having a SFC 20 of at least about 40 weight percent and contains no more than about 10 weight percent, e.g., 5 weight percent or less, *trans*-fatty acids. In one particular implementation, the palmoil fat has a SFC 20 of at least about 50 weight percent and a SFC 20 : TFA ratio of at least about 6, e.g., about 10 or higher. The dIV : TFA ratio may be at least about one, preferably two or higher, with dIV : TFA ratios of at least about 3 being preferred for many applications. The partially hydrogenated palmoil fat may have a CFA : TFA ratio of at least about 3 and, optionally, may be no greater than about 20. In some implementations, the C18 : TFA ratio may be at least about two, e.g., 3 or higher, and optionally no greater than about 20, e.g., about 15 or less. Palmoil fats in some embodiments of the invention may have a R 120 induction period of 25 hours or longer, e.g., at least about 40 hours.
- [0093] **Corn Oil:** Still another embodiment of the invention provides a partially hydrogenated corn fat with a SFC 20 of 20-80 weight percent and containing no more than about 20 weight percent, preferably no more than about 15 weight percent, of *trans*-fatty acids.
- [0094] The following examples illustrate aspects of select feedstock hydrogenation processes and edible hydrogenated fats in the context of hydrogenating refined seed oils:

### Hydrogenation Example A – Soybean Oil

- [0095] About 15 metric tons of neutralized, bleached soybean oil was charged into a commercial hydrogenation reactor, heated to about 45° C, and flushed with hydrogen. About 120 kg (0.8 weight percent) of an activated catalyst composition substantially similar to the third exemplary catalyst composition mentioned above was mixed with the soybean oil to form a slurry. The slurry was hydrogenated at about 50-60° C with an iodine value drop of about 10 per hour (as approximated by the rate of hydrogen gas uptake) at a pressure of about 20 bar. Samples quantities were taken periodically at times estimated to yield a hydrogenated fat having a SFC 20 at a target weight percent, e.g., 10, 25, 45, and 70 weight percent.
- [0096] This process was repeated for a second batch of neutralized, bleached soybean oil, but with a couple of variations. In particular, the second batch included about 30 kg (0.2 weight percent, versus about 0.8 weight percent) of the same catalyst composition and was hydrogenated at a temperature of about 72-90° C (versus about 50-60° C).
- [0097] For purposes of comparison, a third batch of neutralized, bleached soybean oil was hydrogenated in a more conventional fashion. This batch included about 0.08 weight percent of commercial PRICAT 9920 and was hydrogenated at about 180° C and a pressure of about 3 bar-a at an iodine value drop of about 20 per hour.
- [0098] Tables A1 – A4 list select physical properties and aspects of the fatty acid profile of the soybean oil at selected points during the course of hydrogenation, with the data under the heading S180 corresponding to the conventional hydrogenation at 180° C, the data under the heading S50 corresponding to the 50° C hydrogenation, and the data under the heading S72 corresponding to the 72° C hydrogenation:

- [0099] Figure 3 is a plot of variation of the *trans*-fatty acid content with the Iodine Value for each of these three batches. This figure graphically highlights the remarkable difference in *trans*-fatty acid content of conventionally hydrogenated soybean oil and the soybean oil hydrogenated in accordance with embodiments of the invention. The *trans*-fatty acid content of the conventionally hydrogenated oil increases quite rapidly from an initial value of nearly 0 weight percent to greater than 40 weight percent. Neither of the batches hydrogenated with a catalyst composition in accordance with embodiments of the invention exceed 13 weight percent, less than a third of the maximum for the conventionally hydrogenated product. The S50 batch had a *trans*-fatty acid content of about 8 weight percent, about one fifth that of the conventional S180 batch.

- [00100] A partially hydrogenated soybean fat in accordance with one embodiment of the invention has a solid fat content at 20°C of at least about 20 weight percent (e.g., about 20-80 weight percent) and a *trans*-fatty acid content of no greater than about 15 weight percent, more desirably no greater than about 10 weight percent. Both the S50 and the S72 batches have *trans*-fatty acid content of less than 15 weight percent throughout the measured range of Iodine Values. Likely because of its lower hydrogenation temperature, the S50 batch maintains an even lower *trans*-fatty acid content, with a maximum of 8 weight percent. As discussed above, hydrogenation in select embodiments is conducted at a temperature no greater than about 80° C, e.g., 50° C or less. Figure 3 demonstrates that the S50 batch consistently maintained a *trans*-fatty acid content below that of the S72 batch.
- [00101] The S50 batch also demonstrates that embodiments of the invention can reduce the Iodine Value of an oil by more than 50 (from 135 to 80) in an industrial setting while increasing the *trans*-fatty acid content by no more than about 6 weight percent. In particular, the ratio of the absolute value of the decrease in Iodine Value to the increase in *trans*-fatty acid content on a weight percent basis (dIV : TFA in Tables A1-A4) is between 9 and 10 for this particular experimental example. Although this ratio varies somewhat over the course of hydrogenation, the ratio starts out quite high (about 15) then remains generally between about 9 and about 11 over the course of the measured Iodine Values. The dIV : TFA ratio for the S72 batch remains above 5 over the range of measured values, but the conventionally hydrogenated S180 never exceeded about two over the same range. Since the change in Iodine Value correlates to the degree of hydrogenation, a higher dIV : TFA ratio is desirable in that less *trans*-fatty acid is present at the same degree of hydrogenation. In one embodiment of the invention, the dIV : TFA ratio is at least about 5, e.g., about 7 or greater, for partially hydrogenated fats having a SFC 20 of about 20-80 weight percent; such a fat having a dIV : TFA ratio of at least about 9 is expected to be useful for many applications.

### Hydrogenation Example B – Canola Oil

- [00102] About 15 metric tons of neutralized, bleached, deodorized canola oil was charged into a commercial hydrogenation reactor, heated to about 45° C, and flushed with hydrogen. About 60 kg (about 0.4 weight percent) of an activated catalyst composition substantially similar to the third exemplary catalyst composition mentioned above was mixed with the canola oil to form a slurry. The slurry was hydrogenated at about 45° C with an Iodine Value drop of about 10 per hour at a pressure of about 20 bar. Samples were taken periodically at times estimated to yield a hydrogenated fat having a SFC 20 at target weight percents of 10, 20, 35, and 55 weight percent. This process was repeated for a second batch of neutralized, bleached, deodorized canola oil, but the second batch included about 15 kg (0.1 weight percent versus about 0.4 weight percent) of the same activated catalyst composition and was hydrogenated at a temperature of about 72° C (versus about 45° C). A third batch of neutralized, bleached, deodorized canola oil was hydrogenated in a more conventional fashion. This batch included about 0.12 weight percent of commercial PRICAT 9920 and was hydrogenated at about 180° C and a pressure of about 4 bar-a at an Iodine Value drop of about 20 per hour.
- [00103] Tables B1 – B4 list certain physical properties and aspects of the fatty acid profile of the canola oil at selected points during the course of hydrogenation, with the data under the heading C180 corresponding to the conventional hydrogenation, the data under the heading C45 corresponding to the 45° C hydrogenation, and the data under the heading C72 corresponding to the 72° C hydrogenation:

[00104] The *trans*-fatty acid content is plotted against Iodine Value for each of these three batches in Figure 4. As in the preceding example employing soybean oil, the difference between the conventional hydrogenation and hydrogenation in accordance with embodiments of the invention is striking. The conventionally hydrogenated oil shoots up rapidly from an initial *trans*-fatty acid content of about 1 weight percent to more than 50 weight percent, i.e., more than half of the fatty acid content is *trans*-fatty acid. Over this period, the dIV : TFA ratio remains below 1. After reaching a high of over 50 weight percent *trans*-fatty acid, the *trans*-fatty acid content drops as continued hydrogenation converts some of the *trans*-fatty acids into saturated fatty acids. In contrast, the dIV : TFA ratio for the C45 batch starts at about 15 and remains between about 8 and about 11 over the rest of the range of measured values and the dIV : TFA ratio for the C72 batch starts at about 7.5

and remains between about 4 and about 6 over the rest of the range of measured values. The sharply higher dIV : TFA ratios for the C45 and C72 batches indicate that much less *trans*-fatty acid was produced for a given degree of hydrogenation than in conventional canola oil hydrogenation.

- [00105] Both the C45 and C72 batches had a maximum *trans*-fatty acid content of well under 15 weight percent over the measured range, with the C72 batch remaining no greater than about 10 weight percent *trans*-fatty acid for an Iodine Value change of almost 50 (from 105 to 60) even with a starting oil containing about 1 weight percent *trans*-fatty acid. Of particular note, the C45 sample did not exceed 6 weight percent *trans*-fatty acid at any point over the measured range, suggesting that the hydrogenation process never generated more than 5 weight percent *trans*-fatty acid. This is a full order of magnitude less than the peak *trans*-fatty acid content of the conventionally hydrogenated sample.
- [00106] These examples suggest that aspects of the low-temperature hydrogenation processes outlined above can be used beneficially for a variety of products. In the context of edible fats, for example, embodiments of the invention provide products that often have *trans*-fatty acid contents less than 15, e.g., no more than about 10, which can be less than half, and as little as 10%, of the *trans*-fatty acid content produced in a more conventional process. In addition, the ratio of *cis*- to *trans*-C18:y acids in embodiments of the invention is often at least about double the same ratio for a more conventionally processed product. Both of these factors suggest that embodiments of the invention have a better *trans* selectivity than conventional processes. Further embodiments of the invention also yield partially hydrogenated edible fats having a ratio of saturated C18 to *trans*-fatty acids at least about double, and commonly 5-10 times, that of analogous conventionally hydrogenated products.

#### E. Edible, Partially Hydrogenated Fat Compositions

- [00107] Further embodiments of the invention contemplate fat compositions that may incorporate partially hydrogenated fats such as those discussed in Section D. As noted above, the hydrogenated fats may be at least semi-solid at about 20-25° C,

with a SFC 20 of about 20-80 weight percent, preferably about 25-75 weight percent, and a *trans*-fatty acid content of no greater than about 20 weight percent, e.g., 4-20 weight percent, preferably no greater than about 15 weight percent, e.g., 5-10 weight percent. Such fats may be used in a wide variety of fat compositions, including but not limited to margarines, spreads, shortenings, bakery fats, cream filling fats, frying fats; choco spreads, powdered fats, and animal feeds.

- [00108] One embodiment of the invention provides a shortening composition that includes a partially hydrogenated shortening fat having a SFC 20 of about 20-80 weight percent and a *trans*-fatty acid content of no more than about 20 weight percent, e.g., about 4-20 weight percent, and preferably no more than about 15 weight percent, e.g., about 5-10 weight percent. This shortening fat may comprise one of the fats outlined above, e.g., a partially hydrogenated soy fat or canola fat in accordance with the embodiments outlined in Section D above. The shortening composition may also include a variety of other ingredients commonly employed in edible shortenings and may be blended with those ingredients in known processes. For example, the shortening fat may comprise a partially hydrogenated fat as noted above and another fat, e.g., a food oil, a partially hydrogenated food oil, or a fully hardened food oil. The shortening composition may employ any of a variety of known antioxidant systems, e.g., tocopherol, TBHQ, BHT, or propyl gallate. It may also include metal scavengers such as citric acid, phosphoric acid, and EDTA to increase the stability of the shortening composition. The shortening composition may also be blended with one or more conventional shortening emulsifiers, typically by physical blending. These emulsifiers include, for example, lecithin, diacetylated tartaric acid esters of monodiglycerides, and sodium stearoyl lactylate.
- [00109] Another embodiment of the invention provides a margarine or spread composition that includes a margarine fat in accordance with an embodiment of the invention. Such a margarine fat desirably has a SFC 20 of about 20-80 weight percent and a *trans*-fatty acid content of no more than about 20 weight percent, preferably about 4-15 weight percent, e.g., about 5-10 weight percent. If so desired, the margarine fat may also include a structuring fat. Such structuring fats are well known in the

art and may include, for example, lauric fats, e.g., palmoil, palmolein, coconut oil, a stearin fraction of such an oil, or interesterified mixtures of such oils. The margarine fat may, in addition to or instead of the structuring fat, include a hardstock fat, such as a fully hardened edible oil. The margarine or spread composition may include the margarine fat and a dispersed aqueous phase and have a plastic rheology. The margarine or spread composition may also include minor amounts of other additives, e.g., antioxidants such as those noted above, emulsifiers such as those noted above, vitamins, colorants, or flavorants. The aqueous phase may include any of a variety of conventional compositions, e.g., any one or more of water, milk components (e.g., soured milk or buttermilk), flavor preservatives, and food acids.

- [00110] The above-detailed embodiments and examples are intended to be illustrative, not exhaustive, and those skilled in the art will recognize that various equivalent modifications are possible within the scope of the invention. For example, whereas steps are presented in a given order, alternative embodiments may perform steps in a different order. The various embodiments described herein can be combined to provide further embodiments.
- [00111] In general, the terms used in the following claims should not be construed to limit the invention to the specific embodiments disclosed in the specification unless the preceding description explicitly defines such terms. The inventors reserve the right to add additional claims after filing the application to pursue additional claim forms for other aspects of the invention.

## CLAIMS

1. A method of partially hydrogenating an unsaturated fat, comprising:  
dispersing a nickel-based catalyst in an unsaturated edible oil, the edible oil  
having an initial Iodine Value and an initial fatty acid content;  
delivering hydrogen to the oil; and  
hydrogenating the oil at a hydrogenation temperature no greater than about  
70° C for a hydrogenation time to yield a partially hydrogenated fat having  
a modified Iodine Value and including a modified fatty acid content,  
wherein the partially hydrogenated fat has a solid fat content of about 25-  
80 weight percent at 20° C, an absolute difference between the initial  
Iodine Value and the modified Iodine Value (dIV) divided by the  
hydrogenation time defines an average Iodine Value change rate of no  
less than about 5/hour, and no more than about 15 weight percent of the  
modified fatty acid content comprises *trans*-fatty acids.
2. The method of claim 1 wherein the oil is at the hydrogenation temperature  
when initiating the hydrogenation and the oil is hydrogenated without adding  
external heat.
3. The method of claim 1 wherein hydrogen is delivered to the oil before  
dispersing the nickel-based catalyst in the oil.
4. The method of claim 1 wherein the hydrogenation temperature is no greater  
than about 50° C.
5. The method of claim 1 wherein the hydrogenation temperature is about 20-50°  
C.

6. The method of claim 1 wherein the hydrogenation temperature changes over the course of the hydrogenation time, the hydrogenation reaction being initiated at a hydrogenation temperature no greater than about 50° C.
7. The method of claim 1 wherein the hydrogenation temperature changes over the course of the hydrogenation time, the hydrogenation reaction being initiated at a hydrogenation temperature no greater than about 50° C and the hydrogenation temperature not exceeding about 70° C during the hydrogenation time.
8. The method of claim 1 wherein the average Iodine Value change rate is between about 6/hour and about 30/hour.
9. The method of claim 1 wherein delivering hydrogen to the oil comprises delivering a gas consisting essentially of hydrogen.
10. The method of claim 1 wherein the nickel-based catalyst is substantially the only catalyst source during the hydrogenation of the oil.
11. The method of claim 1 wherein a total *trans*-fatty acid increase is a difference between the weight percent of the *trans*-fatty acids in the partially hydrogenated fat and an initial *trans*-fatty acid weight percent of the initial fatty acid content, wherein the ratio of dIV to the *trans*-fatty acid increase is at least about 5.
12. An edible fat composition formed by the process of claim 1.
13. A method of hydrogenating an edible oil having an initial solid fat content of less than 20 weight percent at 20°C, an initial Iodine Value, and an initial fatty acid content, the method comprising:  
providing a catalyst composition including a fat component and a nickel-based catalyst that has been activated by heating to a first temperature;

dispersing the catalyst composition in the oil;  
delivering hydrogen to the oil; and  
hydrogenating the oil at a second temperature to yield a partially hydrogenated fat having a modified Iodine Value and including a modified fatty acid content, wherein:  
the second temperature is less than the first temperature;  
the partially hydrogenated fat has a solid fat content of about 20-80 weight percent at 20° C;  
an absolute difference between the initial Iodine Value and the modified Iodine Value (dIV) divided by the hydrogenation time defines an average Iodine Value change rate of about 6-40/hour; and  
no more than about 15 weight percent of the modified fatty acid content comprises *trans*-fatty acids.

14. The method of claim 13 wherein dispersing the catalyst composition comprises contacting the catalyst composition, which is at a third temperature, with the oil, the third temperature being greater than the second temperature and at least as great as a melting point of the fat composition.
15. A partially hydrogenated fat selected from a group consisting of partially hydrogenated soybean oil and partially hydrogenated canola oil, the partially hydrogenated fat having:  
a solid fat content of at least about 20 weight percent at 20° C;  
a *trans*-fatty acid content of about 4-20 weight percent; and  
a ratio of C18 content to the *trans*-fatty acid content (C18 : TFA) of at least about one.
16. The partially hydrogenated fat of claim 15 wherein the C18 : TFA ratio is at least about two.

17. The partially hydrogenated fat of claim 15 wherein the C18 : TFA ratio is at least about 4.
18. The partially hydrogenated fat of claim 15 wherein a ratio of the solid fat content at 20° C to the *trans*-fatty acid content is at least about two.
19. The partially hydrogenated fat of claim 15 wherein a ratio of the solid fat content at 20° C to the *trans*-fatty acid content is at least about 4.
20. The partially hydrogenated fat of claim 15 wherein the partially hydrogenated oil had an initial Iodine Value prior to hydrogenation and the partially hydrogenated fat has a final Iodine Value, a ratio of the absolute value of a difference between the initial and final Iodine Values to the *trans*-fatty acid content is at least about 4.
21. A partially hydrogenated fat selected from a group consisting of partially hydrogenated soybean oil and partially hydrogenated canola oil, the partially hydrogenated fat having:
  - a solid fat content of at least about 20 weight percent at 20° C;
  - a *trans*-fatty acid content of about 4-20 weight percent; and
  - a ratio of the solid fat content at 20° C to the *trans*-fatty acid content (SFC 20 : TFA) of at least about two.
22. The partially hydrogenated fat of claim 21 wherein the SFC 20 : TFA ratio is at least about 4.

**LOW TRANS-FATTY ACID FATS AND FAT COMPOSITIONS AND METHODS  
OF MAKING SAME**

**ABSTRACT OF THE DISCLOSURE**

This disclosure describes select low *trans*-fatty acid fats and fat compositions and methods of making such fats and fat compositions. These fats and fat compositions achieve organoleptic properties commonly associated with typical partially hydrogenated fats, but avoid the high *trans*-fatty acid contents typically associated with such fats.
